A Clinical Update On An Alternative Vascular Access For the CATHETER-DEPENDENT HEMODIALYSIS PATIENT

What is the order of preference for vascular access options in hemodialysis?

The gold standard for vascular access in hemodialysis patients is the arteriovenous fistula (AVF). The 2006 KDOQI Clinical Practice Guidelines for Vascular Access in Hemodialysis state the order of preference for vascular access as:

- Arteriovenous fistulae are preferred;
- Arteriovenous grafts (AVG) made of synthetic or biological material are acceptable;
- Short and long-term tunneled dialysis catheters (TDC) should be avoided, if possible.

AVFs are associated with the fewest complications and hospitalizations when compared with other access modalities. According to data from the 2007 United States Renal Data System (USRDS), for patients with a catheter, rates of vascular access infection are four times higher than for those who have a graft, and eight times higher than for those who have a fistula. Accordingly, the Fistula First Initiative recommends that catheter use be reduced, and that more patients receive an AVF.

HEMODIALYSIS VASCULAR ACCESS

1. What is the order of preference for vascular access options in hemodialysis?
2. What are options for patients who are not candidates for an arteriovenous fistula or arteriovenous graft due to central venous stenosis or occlusion?
3. What is the HeRO® Graft and its indications for use?
4. What are the evidence-based benefits and risks related to use of the HeRO® Graft?
5. How is patient suitability for the HeRO® Graft determined?
6. How can clinicians best ensure success after graft placement?
What are options for patients who are not candidates for an arteriovenous fistula or arteriovenous graft due to central venous stenosis or occlusion?

For patients who are not candidates for an AVF or conventional AVG, or for those in whom these options have failed, the risk of catheter dependency and other catheter-related problems created significant concerns. TDCs are associated with a high incidence of infectious complications and mortality and should not be used unless all other options have failed. Other problems related to catheters include less effective dialysis secondary to reduced blood flow rates, mechanical complications, and central venous stenosis (CVS) and/or occlusions. Of the 104,252 patients who began hemodialysis in 2009, 82% were using either a catheter alone or a catheter with a maturing AVF or AVG. Ironically, the continued high rate of TDC placement, with increased risk of CVS or occlusions may even reduce the placement of a permanent dialysis access, and thus increase the number of patients dependent upon TDCs for chronic dialysis.1,2

CVS or if a stenosis recurs within a 3-month period.1 When there is the need for more than two angioplasty procedures within a 3-month interval, surgery may be considered.3 More severe forms may be treated by ligation of the AVG or AVG, or use of the HeRO graft, a device that was studied in a multicenter clinical trial demonstrating a statistically significant reduction in bacteremia rates compared with CVCLs.4 If these options fail, a change in renal replacement modality to either peritoneal dialysis or renal transplant should be considered.5

This resource focuses on The Hemodialysis Reliable Outflow (HeRO®) Graft, an alternative for vascular access in select hemodialysis patients who are catheter-dependent.

What is the HeRO® Graft and its indications for use?

The HeRO Graft is a long-term fully subcutaneous dialysis device that instead of a venous anastomosis, utilizes an outflow component that traverses central venous stenosis to provide continuous outflow into the central venous system.6 It was cleared for use by the Food and Drug Administration (FDA) in 2008, and was classified as a graft. The FDA states that it is indicated for end-stage renal disease patients on hemodialysis who have exhausted all other access options.7

The device has two parts: a 4-mm expanded polytetrafluoroethylene (ePTFE) graft to be anastomosed to a peripheral artery at one end with a titanium connector at the other end that connects with a 19F silicone tube (outer diameter of 6.3 mm, and inner diameter of 5 mm) that is reinforced with a nitinol braid to prevent kinking.8 Like standard prosthetic access devices, the HeRO is cannulated by inserting dialysis needles into the graft component once the graft is tissue incorporated.9

How is patient suitability for the HeRO Graft determined?

Patients should be evaluated for HeRO Graft placement if they have become catheter-dependent or are approaching catheter-dependency because all other peripheral access options have been exhausted. Poor venous outflow should be determined by a history of previous access failures and venography. Failing fistulas or grafts can be suspected to have poor venous outflow by the presence of decreased Kt/V, swollen access arm, and/or collateral vein development. A compromised central venous system or central venous stenosis should be determined by vessel mapping, preferably venography. The preoperative evaluation should include upper extremity arterial and venous duplex studies. If a central venous stenosis or occlusion is suspected from the venous duplex, a central venogram may be needed to clarify venous anatomy before determining the appropriate treatment and/or placing the device. Additionally, a catheter-based arteriogram or CT arteriogram may be helpful if there is any suspicion of an arterial inflow problem at the proposed anastomotic site based on the non-invasive imaging.1

Based upon diagnostic findings, the nephrologist may refer the patient to a vascular surgeon, or if an interventionalist, may perform the optimal procedure(s). The treatment choice should be based, in part, upon perceived life expectancy, dialysis access longevity, and other co-morbid factors.1

Potential candidates will have:

- exhausted peripheral venous access sites suitable for fistulas or grafts
- a brachial artery diameter of ≥ 3 mm
- cardiac ejection fraction of > 20%
- systolic blood pressure > 100 mm Hg
- absence of infection as determined by negative blood culture

How can clinicians best ensure success after HeRO Graft placement?

Post-placement infection can be prevented by removing the bridging catheter as soon as possible and treating prophylactically with broad spectrum antibiotics. Prophylactic intravenous antibiotic therapy tailored to local bacterial experience should be considered if the patient is at increased risk for infection. Clotting of these grafts occurs and is thought to be related primarily to hypotension as this device is long (90 cm untrimmed). In order to promote adequate blood flow through the HeRO, it is recommended that the patient maintain a systolic blood pressure of >100 mm Hg and an ejection fraction of > 20%.10 Blood pressure trends should be evaluated post-placement and the use of antihypertensive drugs reviewed. Testing for hypercoagulability is indicated if suspected and should be treated with anticoagulants as needed. As with any peripheral access, avoid the use of fistula clamps after needle removal to prevent prolonged pressure on the graft.11

Thrombectomy is relatively quick and uncomplicated should it be necessary. Specific guidelines for using this device are available.

The "Three Rights to HeRO Graft Success”11

1. The Right Patient
- Bilateral central venous patholoy
- Adequate cardiac function
- Infection-free

2. The Right Surgeon
- Endovascular skills (or partnered with an interventionalist)
- Commited and experienced

3. The Right Management by the Interdisciplinary Team
- Assessment and cannulation as per KDQI Guidelines for Prevention of access thrombosis and infection

---

**Adequacy of Dialysis**

- systolic blood pressure of 100 mm Hg
- cardiac ejection fraction of >20%
- absence of infection as determined by negative blood culture
For patients who are not candidates for an AVF or conventional AVG, or for those in whom these options have failed, the risk of catheter dependency and other catheter-related problems creates significant concern. TDCs are associated with a high incidence of infectious complications and mortality and should not be used unless all other options have failed. Other problems related to catheters include less effective dialysis secondary to reduced blood flow rates, mechanical complications, and central venous stenosis (CVS) and/or occlusions.5 Of the 104,252 patients who began hemodialysis in 2009, 82% were using either a catheter alone or a catheter with a mature AVG or AVF.6,7 Ironically, the continued high rate of TDC placement, with increased risk of CVS or occlusions may eventually preclude the placement of a permanent dialysis access, and thus increase the number of patients dependent upon TDCs for chronic dialysis.6,7 CVS leads to outflow obstruction of AVGs or AVFs, severe venous hypertension, arm swelling, and compromise of upper limb access.8,9 KDQOI recommends percutaneous intervention with transluminal angioplasty as the preferred treatment for CVS.8 Stent placement combined with angioplasty is indicated in elastic CVS or if a stenosis recurs within a 3-month period.10 When there is the need for more than two angioplasty procedures within a 3-month interval, surgery may be considered.11 More severe forms may be treated by ligation of the AVG or AVG, or use of the HeRO Graft, a device that was studied in a multicenter clinical trial demonstrating a statistically significant reduction in bacteremia rates compared with CVLS.12 If these options fail, a change in renal replacement modality to either peritoneal dialysis or renal transplant should be considered.13

What is the HeRO® Graft and its indications for use?

The HeRO® Graft is a long-term fully subcutaneous dialysis device that instead of a venous anastomosis, utilizes an outflow component that traverses central venous stenosis to provide continuous outflow into the central venous system.14 It was cleared for use by the Food and Drug Administration (FDA) in 2008, and was classified as a graft. The FDA states that it is indicated for end-stage renal disease patients on hemodialysis who have exhausted all other access options.15

The device has two parts: a 4-mm expanded polytetrafluoroethylene (ePTFE) graft to be anastomosed to a peripheral artery at one end with a titanium connector at the other end that connects with a 19F silicone tube (outer diameter of 6.3 mm, and inner diameter of 5 mm) that is reinforced with a nitinol braid to prevent kinking. Figure 1. Like standard prosthetic access devices, the HeRO® is cannulated by inserting dialysis needles into the graft component once the graft is tissue incorporated.6
