Dialysis Outcomes and Practice Patterns Study

NKF DOPPS WebEx

Nancy Ginsberg MSRD,
Arbor Research Collaborative for Health
Contact info: nancy.ginsberg@fmc-na.com

Web Conference
June 17, 2010

Agenda

1. DOPPS study design
2. DOPPS data collection
3. DOPPS nutritional studies: prior results
4. Future research opportunities in DOPPS
Dialysis Outcomes and Practice Patterns Study (DOPPS)

- International prospective cohort study of hemodialysis patients and HD unit practices
- Uniform international data collection
- **Goal**: Identify HD practice patterns associated with improved patient outcomes (adjusted for patient mix)
- **Major outcomes**: mortality, hospitalization, vascular access, quality of life
- DOPPS is supported by scientific research grants from Amgen (since 1996), Kyowa Hakko Kirin (since 1999, in Japan), Genzyme (since 2009), and Abbott (since 2009) without restrictions on publications
- Coordinated by the Arbor Research Collaborative for Health (Ann Arbor, MI USA)
A Decade of DOPPS

* Japan, US, Europe (France, Germany, Italy, Spain, UK) + Australia, Belgium, Canada, New Zealand, Sweden

** Includes oversampling of small, rural, independent facilities in US
DOPPS Sampling Protocol

**Goal:** A representative sample of dialysis facilities and patients from each country

**Methodology**

- Randomized selection among all facilities
- Exclude small facilities (< 25 in-center HD pts, affects ≤ 5% of HD patients in a country)
- Random selection stratified to ensure proportional representation by geographic region and facility types within each country

**What is Unique About DOPPS?**

- Nationally representative, 12 countries
- Uniform data collection
- In depth assessment of comorbidities, practices, lab values, and medications
- Timeliness of the data
- Longitudinal data, time trends

DOPPS Data Collection Overview

DOPPS Data Collection

- The DOPPS use a number of study instruments to gather detailed data on facilities and patients:
  - Cumulative Hemodialysis Census, demographic and outcomes data from all chronic HD patients in a facility during the study
  - Medical Questionnaire, baseline medical information
  - Interval Summary, longitudinal data, monthly laboratory data
  - Patient Questionnaire, patient-reported data (e.g., QoL)
  - Termination Form
  - Unit Practices Survey and Medical Directors Survey, providing detailed facility practice information

- Selected details are provided on the following slides.
DOPPS Nutrition-Related Data

• For each patient, data on pre- and post-dialysis weight are collected for three consecutive HD sessions during the reporting interval

• Nutritional indicators collected monthly: total protein, s. albumin, creatinine, BUN, nPCR, phosphorus & lipid panel

• Question on undernourished or cachectic appearance

• Data on oral nutritional supplement use, intradialytic parenteral nutrition and multi-vitamin prescription collected every four months

• Prior DOPPS special nutrition study in the US and Japan collected patient self-administered food frequency questionnaires (FFQ)

More DOPPS publications and slide downloads are available at:

www.dopps.org
Serum Albumin

• Patients with serum albumin concentrations <3.5 g/dL had 1.38 times the mortality risk of patients with higher concentrations, even after controlling for demographics and comorbid conditions.

• Patients had higher mortality risks following a six-month period with a decline in serum albumin concentration, supporting the recommendation to measure ESRD patients’ serum albumin regularly.
Modified Subjective Global Assessment (mSGA)

- The DOPPS found wide and significant differences among countries in the proportions of both moderately and severely malnourished ESRD patients\(^1\) (Table 1).
- In the US, severely malnourished ESRD patients had a 25% higher mortality risk (after adjustment for demographics and comorbid factors) than patients with normal mSGA scores (Table 2).

\(^1\) Based on a mSGA determined using DOPPS data on caregiver responses to questions about patient weight loss and physical appearance and on patient responses to questions about appetite, nausea, energy level, and disease burden. Combe C et al. *Am J Kidney Dis* 44 (Suppl 2):S39-S46, 2004

Serum Creatinine

- In the US and Europe, the DOPPS found mortality risk to be inversely associated with baseline serum creatinine concentration (60%-70% higher for patients with serum creatinine levels in the lowest quartile than those in the quartile with the highest level).
- Mortality risk was also higher following a decrease in serum creatinine concentration over a six-month period.
- Because there is no clear threshold value for serum creatinine concentration, serial measurements remain highly useful for measuring nutritional status and predicting outcomes.

Figure 1. Mortality versus BMI, Euro- and US-DOPPS

**Conclusion**

- DOPPS findings on various nutritional indicators highlight the importance of routinely assessing nutritional status using multiple parameters. Monitoring nutritional status with a variety of means and in accordance with clinical practice guidelines can help predict outcomes and improve patient care.

Lack of Appetite in Haemodialysis Patients-Associations with Patient Characteristics, Indicators of Nutritional Status and Outcomes in the International DOPPS

_Nephrology Dialysis Transplantation 22: 3538-3546, 2007_

---

**Introduction**

- Malnutrition highly prevalent and strongly associated with higher mortality risk in haemodialysis (HD) patients
- Low food intake contributes to this malnutrition
- Early identification of patients with eating behaviour disturbances could improve HD outcomes
- Use of food frequency questionnaires and food diaries not practical in clinical setting
- Data from DOPPS I and II used to explore relationship between single lack of appetite question and nutritional status, inflammatory markers morbidity, and mortality

Methods [1]

• Sample: 14,406 patients from 12 countries enrolled in DOPPS I and II

• Variables of interest:
  – Lack of appetite
    • KDQOL-SF: ‘To what extent were you bothered during the last four weeks by lack of appetite’
  – Nutritional status
    • BMI, serum albumin, serum creatinine, normalized protein catabolic rate
  – Depression
    • ‘Have you felt so down in the dumps that nothing could cheer you up?’ (KDQOL-SF)
    • ‘Have you felt downhearted and blue’ (KDQOL-SF)
    • 10 item Center for Epidemiological Studies Depression Screening Index (CES-D)
  – Inflammation
    • Neutrophil and white blood cell counts

Prevalent patient characteristics by categories of bothered by lack of appetite

* P-value for trend across degree that the patients were bothered by lack of appetite; for Kt/V the P-value trend from somewhat to extremely bothered was not significant- P=0.42 (DOPPS I and II)

Association between being bothered by lack of appetite and indicators of nutritional status [1]

- **Albumin** (≤ 3.5 vs > 3.5 mg/dL)
  - P-values < 0.03 for all data points compared to their respective references
  - Odds ratios are adjusted for facility clustering, age, sex, black race, years on dialysis, 14 summary comorbid conditions and country; n=14406 (DOPPS I and II)

- **Creatinine** (≤ 7.5 vs > 7.5 mg/dL)

- **BMI** (≤ 20 vs > 20)

Association between being bothered by lack of appetite and indicators of nutritional status [2]

- **nPCR** (≤ 0.9 vs > 0.9 mg/dL)
  - P-values < 0.03 for all data points compared to their respective references
  - Odds ratios are adjusted for facility clustering, age, sex, black race, years on dialysis, 14 summary comorbid conditions and country; n=14406 (DOPPS I and II)

- **BMI** (≤ 20 vs > 20)
Relative risk of death by degree of being bothered by lack of appetite

Cox models stratified by country and adjusted for facility clustering, age, sex, race, years on dialysis, physician-diagnosed depression and 13 comorbid conditions; n=14,399 (DOPPS I and II)

### Conclusion

- **Being bothered by lack of appetite is a dose-dependent, significant predictor of hospitalization and mortality**
  - RR (mortality) = 2.23 (1.90-2.62)
  - RR (hospitalization) = 1.33 (1.19-1.48)
  
  Comparing patients extremely bothered by lack of appetite vs. patients not bothered at all

- **Depression, nutritional status markers, and inflammation markers were all independently associated with higher odds of being bothered by lack of appetite**

- **A single question about lack of appetite helps identify HD patients with poorer nutrition status, inflammation, depression, and higher risks of hospitalization and death**

- **The possible beneficial effect of longer HD on appetite should be further explored**

- **Country differences in lack of appetite deserve further study**

Introduction

• Serum albumin, serum creatinine, body mass index (BMI), and normalized protein catabolic rate (nPCR) have been used to assess nutritional status of hemodialysis patients

• Kidney Disease Outcomes Quality Initiative (KDOQI) asserts that none of these measures provides complete evaluation of nutritional status

• KDOQI therefore recommends evaluation of multiple parameters

Relative risks were adjusted for age, sex, race, vintage, 14 summary comorbidities, neutrophil/lymphocyte ratio and dialysis by catheter

Conclusions

• There are important variations by country and patient characteristics in nutritional status indicators

• The joint effects of nutritional indicators on mortality indicate the need to use multiple measurements when assessing the nutritional status of hemodialysis patients

• A greater emphasis on nutritional interventions may improve survival among hemodialysis patients
Nutrition-Related Questions in the Current Phase of DOPPS

DOPPS UPS Dietitian Section

• The Unit Practice Survey (UPS) assesses the facility practices related to nursing, patient care, social services and dietary practices

• Dietary section should be completed by the facility dietitian

• If your unit participates in DOPPS, please be aware that you will be asked to answer this section

Possible Collaborations between CRN and DOPPS

- Analyses of data collected in prior DOPPS phases
  - E.g. ongoing analyses on dietitian-patient ratio
- Potential for additional questions for future DOPPS phases
- Proposals for ancillary studies
Developing a Short Tool for Nutritional Status Screening in HD Patients: the ESRD Dietary Intake Evaluation Tool (ESRD DIET)

PI: Sylvia Ramirez

DOPPS ESRD-DIET

• Aims:

1. To develop a clinically useful brief dietary intake questionnaire for use in the dialysis population.

2. To evaluate the performance of the ESRD DIET against the Willett SFFQ for validity, comparability, & reproducibility.

3. To compare the ability of the ESRD DIET to the Willett SFFQ for identifying dietary patterns and associated intermediate markers of nutrition.

• ESRD DIET is meant to be a clinically useful screening tool for dietary intake rather than a research tool (e.g. Block FFQ or Willett FFQ)
ESRD-DIET Study Design

- Patient subjects (600) will come from a sample of 25 dialysis facilities where facility dietitians have expressed interest in participating in the study (note Council of Renal Nutrition support)

- Questionnaire Development and Pre-testing (questionnaire components based on prior DOPPS pilot study, methodology similar to Prime Screen in general population)

- Questionnaire Administration: two administrations of the Willett SFFQ (once at baseline and at a second time point six months later) and four replicates of the ESRD DIET (four weeks before and four weeks after the SFFQ)

- We seek your support in facilitating questionnaire administration to DOPPS patients
